

Portable Laser Function Generator

Brandon Vasquez & Ciara Kamahele

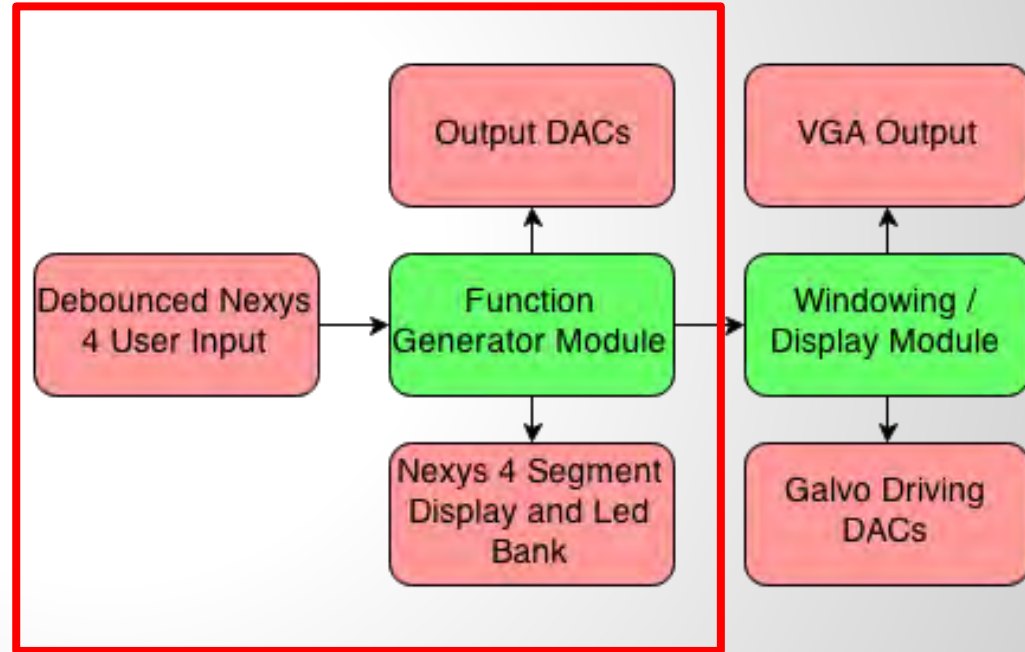

Project Overview

- A functional function generator with multiple viewing modes
- Portable, relatively cheap and easy to assemble

Overall System

Two core modules:

- Waveform generation module responsible for creating a digital representation of a waveform
- Windowing / display module responsible for resizing the waveform to a viewable size and generating the proper display

Function Generator Hardware

Input:

Buttons allow for incrementing and decrementing frequency, amplitude phase and duty cycle

Switches allow for a user to select freq, waveform, frequency increment and phase/duty cycle

Function Generator Hardware

Output:

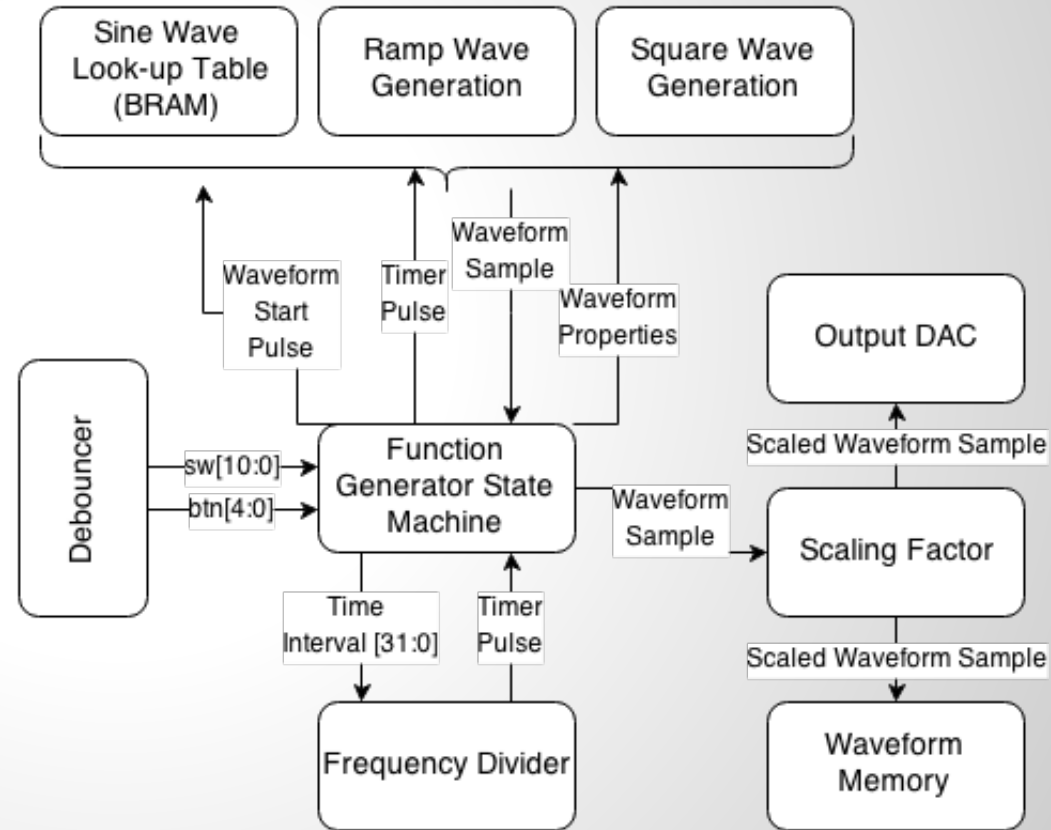

Segment leds will display numerical representation of waveform type, frequency, duty cycle / phase

Output DACs will be connected to one of the user I/O ports

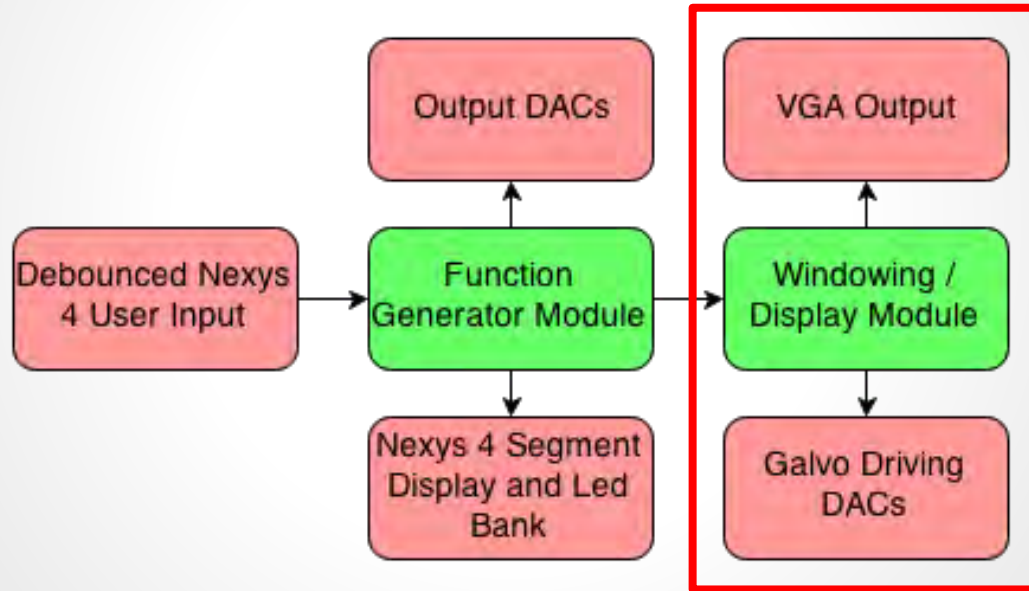

Function Generator Module

- Function Generator State Machine determines waveform and waveform properties with user input
- FSM uses waveform modules to generate waveform
- FSM sends waveform output to scaling factor module which scales amplitude
- Scaled samples are stored in memory and output to DACs

Displaying Hardware and Module

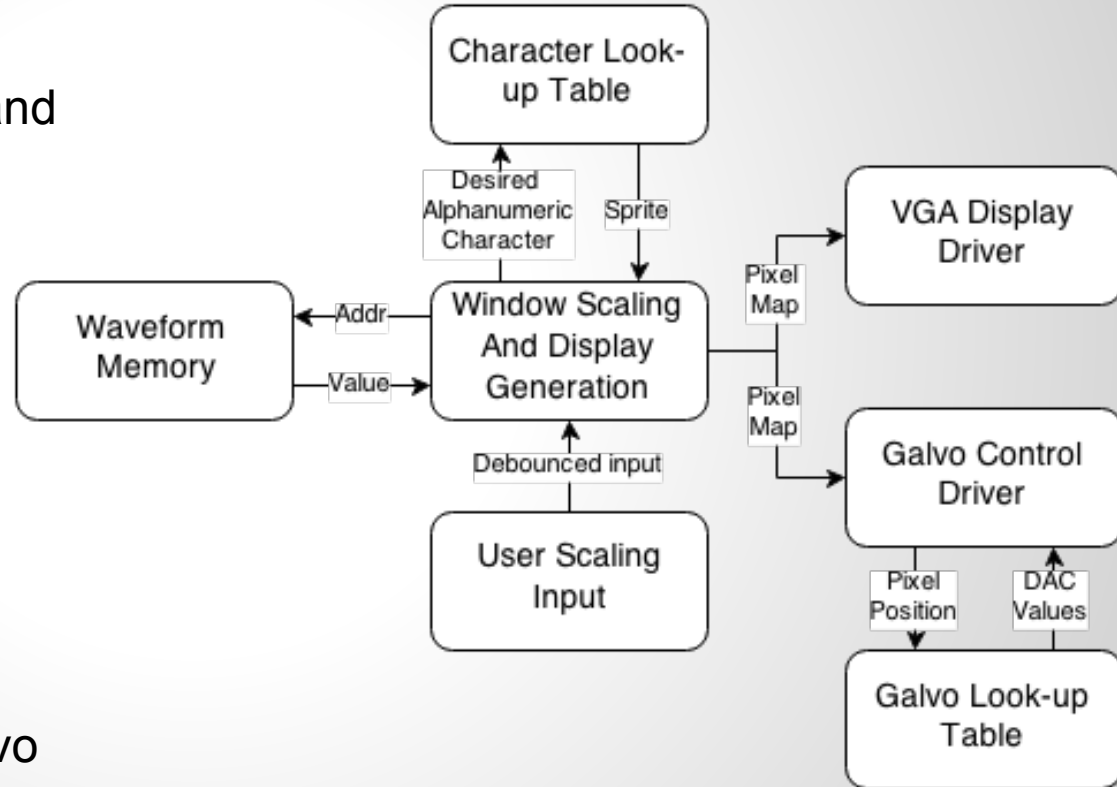

Display Hardware

- VGA Display Interface
- Output DAC for Galvanometers
- Galvanometers

Window and Display Module

- Waveform loaded from waveform memory (BRAM) and scaled using user input
- Added with information regarding waveform with characters from lookup table
- Pixel Map generated and accessible to VGA display driver and galvo control
- Pixel map translated into galvo voltages
